- Gauge Configuration Benefits

## Resistive Gauges

The resistive strain gauge is bonded to the surface so that it deforms with the specimen. The change in length of the bonded gauge causes a change in resistance which is used as a measure of strain.

$$R = \rho_e L / A_c = fn(L, \dots)$$

This is an exaggerated picture so the change is very small...

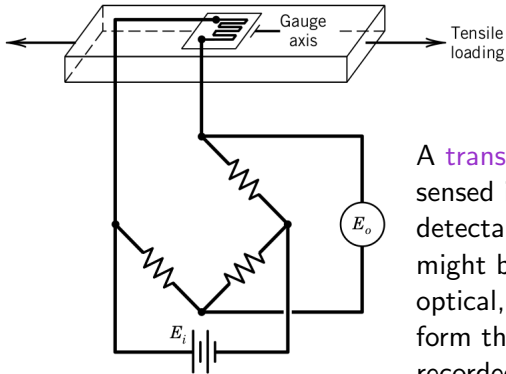

# Resistive Gauges

The **Gauge Factor** is typically used instead of the physical parameters.

$$GF \equiv \frac{\delta R/R}{\delta L/L} = \frac{\delta R/R}{\epsilon_a}$$

This number relates the relative change in resistance to the measured strain.

# The Bridge Circuit

A **transducer** converts the sensed information into a detectable signal. The signal might be mechanical, electrical, optical, or may take any other form that can be meaningfully recorded.

# The Bridge Circuit

How does the bridge circuit work as a transducer?

Use KVL and the voltage divider rule find the relationship between the two voltages.

$$V_b = \left( \frac{R_3}{R_3 + R_4} - \frac{R_2}{R_1 + R_2} \right) \times V_s$$

# Quarter, Half and Full Bridges

# Gauge Configuration Benefits

	Arrangement	Compensation Provided	Bridge Constant $\kappa$
	Single gauge in uniaxial stress	None	$\kappa = 1$
	Two gauges sensing equal and opposite strain—typical bending arrangement	Temperature	$\kappa = 2$
	Two gauges in uniaxial stress	Bending only	$\kappa = 2$
	Four gauges with pairs sensing equal and opposite strains	Temperature and bending	$\kappa = 4$
	One axial gauge and one Poisson gauge		$\kappa = 1 + \nu$
	Four gauges with pairs sensing equal and opposite strains—sensitive to torsion only; typical shaft arrangement.	Temperature and axial	$\kappa = 4$
